

1 Part 1: Theoretical Questions [36 pts]

Submit the solution to this part as Part1.pdf. We can't stress this enough: the file has to be a PDF file.

1. What is the purpose of `valueToLitExp` and what problem does it solve? [4 pts]

Answer: the purpose of `valueToLitExp` is to convert values back into their corresponding expression form. In the applicative order evaluation, arguments need to be evaluated before they can be substituted into expression. This evaluation turns expressions into values. However, when we want to substitute these values back into the original expressions, we need to convert them back into their expression form using `valueToLitExp`. this conversion ensures that we can maintain consistency in the evaluation process and properly replace variables with their corresponding expression and finish the evaluating process.

2. `valueToLitExp` is not needed in the normal order evaluation strategy interpreter (L3-normal.ts). Why? [4 pts]

Answer: In the normal order evaluation strategy interpreter, we don't use `valueToLitExp` because the normal order evaluating delays the evaluation of the arguments until they are needed. This means that the arguments are passed unevaluated expressions (by name and not by value) to the function, and only when we really want them, they are evaluated to values. Thus, there is no need to convert them back to their let-expressions form.

3. What are the two strategies for evaluating a let expression? [4 pts]

Answer:

1) applicative order evaluation this evaluation first evaluates the arguments and then substitute them in the function body for example:

`(let (x 2) (y (+ 2 5)) (+ x y))`

-> in this case the applicative order will evaluate `(+ 2 5)=7` and then substituting the x,y values in the body.

2)normal order evaluation first we don't evaluate the arguments before evaluating the body so we keep them the way they are and when we actually need them we evaluate them. For example:

(let (x 2) (y (+ 2 5)) (+ x y))

-> in this case the normal order will first substitute the variables as they are in the body ((+ 2 (+ 2 5)) and then evaluating the body to get to the result.

4. List four types of semantic errors that can be raised when executing an L3 program - with an example for each type. [4 pts]

a) Type error: by multiply a string with a number

(* 5 "5");error

b) number of arguments in function:

((lambda (a b c d) (+ a (* b c d))) 1 2 3);error

c)evaluating an undefined variable:

(* y 5): y is undefined

d)Syntax error:

(define (add a b (/ a b)

5. What is the difference between a special form and a primitive operator? [4 pts]

Answer: Special forms are built-in language constructs with unique evaluation rules that differ from regular function application. They control program flow and syntax, and examples include if, let, define, quote, and lambda. They cannot be redefined or extended by users and play a crucial role in the language's interpreter or compiler. On the other hand, primitive operators are built-in basic operations in a programming language that perform fundamental computations on primitive data types, while special forms are language constructs with unique evaluation rules and syntax that control program flow.

6. What is the main reason for switching from the substitution model to the environment model? Give an example. [4 pts]

Answer: The main reason for switching from the substitution model to the environment model is to improve efficiency and avoid the costly process time of traversing and substituting variables in each recursive call. In the substitution model, when variables are substituted with their values throughout the program, it requires traversing the entire (AST) to substitute their values. This process can be computationally expensive, especially in the case of recursive functions with multiple occurrences of the same variable. For example: (define factorial (lambda (n) (if (= n 0) 1 (* n (factorial (- n 1))))).

When evaluating (factorial 5) using the substitution model, each recursive call requires substituting n with a new value, resulting in traversing the entire (AST) and substituting in multiple places within the expression (if (= n 0) 1 (* n (factorial (- n 1)))).

The environment model, on the other hand, addresses this issue by maintaining a separate environment or symbol table that stores variable bindings. Instead of repeatedly traversing and substituting variables, the environment model performs efficient variable lookup in the environment. This avoids the need for costly substitutions in each recursive call, resulting in improved efficiency.

7. What is the main reason for implementing an environment using boxes? [4 pts]

Answer: Using boxes in the environment model is to enable mutable state within the environment. This means that we can update and change data dynamically during the program execution. So this has a variety of advantages to our program for example: Dynamic Updates, Flexibility, Efficient Memory Management, Mutable State Handling and Shared Access to data in some boxes.

-
- The diagram illustrates the evaluation of the lambda expression $(\lambda (f) (\lambda (x) (f (f x)))) (\lambda (y) (\lambda (x) (x y))) 2$. It uses a box-and-pointer notation with environment pointers (E_1, E_2, E_3) and binding tables (B_1, B_2, B_3, B_4, B_5) to track the state of the environment during evaluation.
- Initial State:** Environment pointer E_1 points to an empty binding table B_1 . The global environment pointer GE also points to B_1 .
 - Function Application:** The expression is a function application. The function part is $(\lambda (f) (\lambda (x) (f (f x))))$ and the argument is $(\lambda (y) (\lambda (x) (x y))) 2$.
 - Environment Updates:**
 - E_2 is created, pointing to B_2 . B_2 contains the binding $f \rightarrow (\lambda (f) (\lambda (x) (f (f x))))$. GE now points to B_2 .
 - E_3 is created, pointing to B_3 . B_3 contains the binding $x \rightarrow 2$. GE now points to B_3 .
 - Evaluation Flow:**
 - The function $(\lambda (f) (\lambda (x) (f (f x))))$ is evaluated, returning a new environment E_4 with binding table B_4 . B_4 contains $f \rightarrow (\lambda (y) (\lambda (x) (x y)))$ and $x \rightarrow 2$. GE points to B_4 .
 - The argument $(\lambda (y) (\lambda (x) (x y))) 2$ is evaluated, returning a new environment E_5 with binding table B_5 . B_5 contains $y \rightarrow 2$ and $x \rightarrow 2$. GE points to B_5 .
 - The function body $(f (f x))$ is evaluated in environment E_5 .
 - f is looked up in B_5 , returning $(\lambda (y) (\lambda (x) (x y)))$.
 - x is looked up in B_5 , returning 2 .
 - The expression $(f x)$ is evaluated, returning a new environment E_6 with binding table B_6 . B_6 contains $x \rightarrow 2$ and $y \rightarrow 2$. GE points to B_6 .
 - The expression $(f (f x))$ is evaluated, returning a new environment E_7 with binding table B_7 . B_7 contains $x \rightarrow 2$ and $y \rightarrow 2$. GE points to B_7 .
 - Final Result:** The final result is 4 .

2.1.3 Why is bound? expression has to be a special form, and cannot be a primitive or a user function?

The bound? expression requires access to the current environment, which primitive and user-defined functions do not have. Special forms have preferential access to the environment and might provide unique evaluation rules. It is possible to check whether a variable is bound by making bound? a special form and then looking at the environment. This enables the expression to precisely verify variable bindings in the current environment.

2.2.2 Can it be implemented as a user function, primitive or special form?

In contrast to a user function or primitive, the timing tool, denoted by (time cexp>), is often implemented as a special form. User functions and primitives are inappropriate for precise timing since they have no control over the evaluation process and could be impacted by runtime overhead. To accurately monitor execution time, special forms offer the required control and access to start and stop timers at particular times. The language interpreter or compiler can precisely measure and provide time information for code optimization by implementing it as a specific form.
